

Try Catch Error Handling in JavaScript

→In JavaScript, sometimes code can throw errors
(for example: using an undefined variable)

→If we don't handle them, our program crashes.

try...catch is used to safely handle errors so your program can continue running.

What is throw?

→throw is a keyword in JavaScript.

→It is used to manually generate an error.

→When you throw something (usually an Error object), JavaScript immediately stops execution in the try block and jumps to catch.
